

# INF231: Functional Algorithmic and Programming Lecture 3: Advanced types

Academic Year 2019 - 2020

# Defining a type

The general form

```
type t = ... (* possibly with constraints *)
```

Now we are going to see how we can define some more complex types using existing types...

# Outline

#### Synonym types

Enumerated types

Product types

Union/Sum types

Case study: Modelling 4 card games

# Defining a synonym type

Motivations:

- context-specific types
- easier to remember
- re-use

General syntax:

```
type new_type = existing_type
    (* possibly with informative usage constraints *)
```

# Example (Soldes)

- type price = float (\* > 0 \*)
- ▶ type rate = int (\* 0, ..., 99 \*)
- Defining a function to reduce prices:
  - Description: reducedPrice(p,r) is the price p reduced by r%
  - ▶ Profile: reducedPrice: price \* rate → price
  - Examples: reducedPrice(100., 25) = 75.

(note that it is more meaningful than the "anonymous signature" reducedPrice: float \* int  $\rightarrow$  float)

# Do to Understand

#### Example (Soldes)

- type price = float (\* > 0 \*)
- type rate = int (\* 0, ..., 99 \*)
- Defining a function to reduce prices:
  - Description: reducedPrice(p,r) is the price p reduced by r%
  - ▶ Profile: reducedPrice: price \* rate → price
  - Examples: reducedPrice(100., 25) = 75.

(note that it is more meaningful than the "anonymous signature" reducedPrice: float \* int  $\rightarrow$  float)

►

Defining a function to reduce by 10% if she/he is a member of the shop? isMemberPrice (p:price) (m:member):price=...

# Do to Understand

#### Example (Persons)

- Defining a person type which includes name and date. In which:
  - name type comprises first and last,
  - date type comprises month, day and year.

#### Example (Students)

- Defining a student type which includes name, date, university, field, and mean. In which:
  - name type comprises first and last,
  - date type comprises month, day and year,
  - university type is the name of the university,
  - field type is the field that she/he studying,
  - mean type is the average of grades of subjects.

# Outline

Synonym types

Enumerated types

Product types

Union/Sum types

Case study: Modelling 4 card games

### Enumerated types

Motivation: How can we model/define/use:

- the family of a card?  $\{ \blacklozenge, \heartsuit, \diamondsuit, \clubsuit \}$
- the color of a card? {black, white}

From a mathematical point of view: sets defined extensively  $\hookrightarrow$  i.e., by an *explicit enumeration* 

Defining an enumerated type in OCaml:

```
type new_type = Value_1 | Value_2 | ... | Value_n
```

Remark

- Capital letters are mandatory
- new\_type is said to be an enumerated type
- Value\_1, ..., Value\_n are said to be symbolic constants
- Value\_1, ..., Value\_n are of type new\_type
- Implicit order between constants (consequence of the definition)

### Enumerated types: Some examples

Painting / Modelling a card game

#### Example (Some paint colors)

type paint = | Red | Blue | Yellow

# Example (Types of a Card game)

DEMO: types of card game

#### Example (Color of a family)

Returning the color associated to a family card

- ► Description: colorFamily returns the family of a given card.
  - Heart and Diamond are associated to White
  - Spade and Club are associated to Black
- ▶ Signature: colorFamily: family → color
- Examples: colorFamily Spade = Black, ...

# Do to Understand

### Example (Days of week) type dayOfWeek = |Monday

```
Tuesday
```

```
•••
```

### Example (Months of year)

```
type monthOfYear =
| January
| February
| ...
```

# Example (Years)

```
type years =
| 2015
| 2016
| ...
```

# Example (Today)

type today = dayOfWeek, monthOfYear, years

#### Back to the language constructs: **pattern-matching** Your best friend

One of the most powerful feature of OCaml (and functional languages) Pattern-matching: computation by **case analysis** Specified by the following syntax:

```
match expression with
  | pattern_1→ expression_1
  | pattern_2 → expression_2
  ...
  | pattern_n → expression_n
```

Meaning:

 expression is matched against the patterns, i.e., its value is evaluated and then compared to the patterns in order
 "matching" depends on the type of expression!

the expression associated to the first matching pattern is returned

Remark

- First vertical bar is optional
- may use \_ as a wild-card (should be the last pattern)

# (Pattern) Matching on an example

```
Example (colorFamily using if...then...else)
```

```
let colorFamily(f:family):color =
    if (f=Spade || f = Club) then Black
    else (* necessarily f = Heart || f = Diamond *)
    White
```

### Example (colorFamily using pattern-matching)

```
let colorFamily (f:family):color =
  match f with
    | Spade → Black
    | Club → Black
    | Heart → White
    | Diamond → White
```

# (Pattern) Matching on an example

The card game with more concise pattern-matching

Example (colorFamily using a more concise pattern-matching)

```
let colorFamily (f:family):color =
  match f with
  Spade | Club → Black
  | Heart | Diamond → White
```

Example (colorFamily using an even more concise pattern-matching)

```
let colorFamily (f:family):color =
  match f with
   Spade | Club → Black
   |_ → White
```

Example (colorFamily using an even even more concise pattern-matching)

```
let colorFamily = function | Spade | Club \rightarrow Black | _ \rightarrow White
```

# Pattern-matching for enumerated types

#### To the enumerated type

```
type newtype = Value_1 | Value_2 | ... | Value_n
```

is associated the pattern matching

# Rules

- Pattern-matching "follows" the definition of the type (not necessarily with the same order)
- ▶ expression\_i for  $i \in \{1, ..., n\}$  should be of the same type
- Should be exhaustive (or use the wild-card symbol \_)

# Let's practice enumerated types

#### Exercise

- Define the enumerated type month which represents the twelve months of the year
- $\blacktriangleright$  Define the function <code>nb\_of\_days:month</code>  $\rightarrow$  int which associates to each month its number of days

### Matching (also) works (more or less) with (some) predefined types

Pattern-matching is a generalization of the if...then...else...  $\hookrightarrow$  works with existing/predefined types: int, bool, float, char, string

```
Example (Is an integer an even number?)

let is_even (n:int):bool =

match n with

|0 \rightarrow true

|1 \rightarrow false

|2 \rightarrow true

|n \rightarrow if n \mod 2 = 0 then true else false
```

#### Example (Is a character in upper case?)

```
let is_uppercase (c:char) = match c with

'A' \rightarrow true

|'B' \rightarrow true

|...(* 23 conditions *)

|'Z' \rightarrow true

| c \rightarrow false
```

#### Example (Matching with floats is dangerous)

```
match 4.3 - .1.2 with

3.1 \rightarrow \text{true} \rightarrow \text{false} \rightarrow \text{returns false}
```

# Some shortcuts with pattern-matching

For enumerated types

#### "Disjuncting equivalent patterns":

match something with

 $\begin{array}{cccc} & & & & & \\ | p1 \rightarrow v & & & & \\ | p2 \rightarrow v & & & \\ & & & \\ & & & \\ | pm \rightarrow v & & & \\ & & & \\ & & & \\ \end{array} \end{array} \begin{array}{ccccc} \text{match something with} & & \\ & & & \\ & & & \\ | p1 | p2 | pm \rightarrow v & \\ & & \\ & & \\ & & \\ \end{array}$ 

### Example ("Disjuncting equivalent patterns")

# Some shortcuts with pattern-matching - ctd

For characters

"Leveraging the order between characters":

```
\begin{array}{cccc} & \text{match something with} \\ & & & \\ \text{match something with} & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & \\ & & & & & & \\ & & & & & \\ & & & & & \\ & & & & & & \\ & & & & & \\ & & & &
```

where <code>p1, .., pm</code> are *consecutive* characters and <code>p1</code> and <code>pm</code> are the minimal and the maximal characters (not necessarily in this order)

Example ("Leveraging the order between the elements of characters")

```
\begin{array}{ccc} \texttt{let is\_uppercase(c:char)} & \texttt{let is\_uppercase(c:char)} \\ \texttt{= match c with} \\ \texttt{`A' ...`Z' \rightarrow true} & \texttt{or} & \texttt{amatch c with} \\ \texttt{`c \rightarrow false} & \texttt{`z' ...`A' \rightarrow true} \\ \texttt{|c \rightarrow false} & \texttt{|c \rightarrow false} \end{array}
```

# Outline

Synonym types

Enumerated types

#### Product types

Union/Sum types

Case study: Modelling 4 card games

Product type: motivating example(s) and connection with maths

Example (Some complex numbers)

How can we model complex numbers? In maths, we define:

$$\mathbb{C} = \{ a + ib \mid a \in \mathbb{R}, b \in \mathbb{R} \}$$

Z	а	b
3.0 + <i>i</i> * 2.5	3.0	2.5
12.0 + <i>i</i> * 1.5	12.0	1.5
(1.0+i)*(1.0-i)		

Actually, we could also define:

$$\mathbb{C} = \mathbb{R} \times \mathbb{R}$$

The operation  $\times$  is the Cartesian product of sets

#### Example (Defining card)

Same reasoning can be followed if we want to define the type of a card...

# (Cartesian) Product (of) type

We can build Cartesian product of types, i.e., pairs of object of different types:

Type Constructor	Value Constructors
$\alpha*\beta$	•,•
<pre>int*int</pre>	1,2
<pre>int*float</pre>	1,2.0

DEMO: A couple of pairs

Defining new product types:

type new\_type = existing\_type1 \* existing\_type2

Two basic operations on pairs:

- ▶ fst(•1,•2) = •1
- ▶ snd(•1,•2) = •2

Deconstruction on pairs (hidden pattern matching):

let (x1,x2) = (v1,v2) in expression\_using\_x1\_and\_x2

 $\hookrightarrow$  defines the identifiers  $\mathtt{x1}$  and  $\mathtt{x2}$  locally

# General Cartesian product of types

Same principle

Can be generalized to *n*-tuples:

- type definition/construction: let my\_type = type1 \* type2 \* ... \* typen
- value construction: v1,v2,...,vn
- value deconstruction:

let (x1,...,xn) = (v1,...,vn) in expression
(\* expression is depending on x1,...,xn \*)

**DEMO: Generalized Product types** 

# Let's practice product type

#### Exercise: Getting familiar with tuples

- Define the type pair\_of\_int which implements pairs of integers
- Define the function swap which swaps the integers in a pair\_of\_int
- Implement a function my\_fst which behaves as the predefined function fst on pairs\_of\_int

#### Exercise on Complex numbers

- Define the type complex which corresponds to complex numbers
- $\blacktriangleright$  Define function <code>real\_part</code> of type <code>complex</code>  $\rightarrow$  float which returns the real part of a complex number
- $\blacktriangleright$  Define function <code>im\_part</code> of type <code>complex</code>  $\rightarrow$  <code>float</code> which returns the imaginary part of a complex number
- ▶ Define function conjugation: complex  $\rightarrow$  complex Remainder: the conjugation of a + b.i is a b.i

#### Let's practice more Geometry and vectors

#### Exercise on vectors

- Define the type vect which corresponds to vectors in the plane
- $\blacktriangleright$  Define the function <code>sum</code> : <code>vect</code>  $\rightarrow$  <code>vect</code>  $\rightarrow$  <code>vect</code> which performs the sum of two vectors
- What is the type of the function which implements the scalar product?
- ▶ Implement a function which performs the scalar product of two vectors Remainder: scalar product of two vectors  $\vec{u}$ ,  $\vec{v}$ :  $||\vec{u}||.||\vec{v}||.\cos(\vec{u},\vec{v})$ with  $\cos(\vec{u},\vec{v}) = \frac{u_x \cdot v_x + u_y \cdot v_y}{||\vec{u}||.||\vec{v}||}$
- A vector can represent the position of a point in the plane. The rotation of angle θ of a point of coordinates (x, y) around the origin is expressed by the formula:

$$\begin{pmatrix} \cos\theta & -\sin\theta\\ \sin\theta & \cos\theta \end{pmatrix} \cdot \begin{pmatrix} x\\ y \end{pmatrix}$$

Implement the function rotation: float  $\rightarrow$  vect  $\rightarrow$  vect such that rotation angle v makes the vector designated by v rotating of an angle angle

# Outline

Synonym types

Enumerated types

Product types

Union/Sum types

Case study: Modelling 4 card games

# Motivating union types

Mixing carrots and cabbage

... in the context of OCaml type system

Some concepts that we cannot model yet:

- How to build a type figure which can represent circles, triangles, quadrilaterals?
- How to build a type which allows to represent a full color palette ?

How to build a card game which can represent various games?

# Back to the paint

\_

Introducing Union types through an example

Type definition	Filtering
type paint =	let is_blue (p:paint):bool =
Blue  Yellow  Red	match p with
	Blue→true
	Yellow $\rightarrow$ false
	$Red \rightarrow false$

Remark The type paint contains three constant constructors

How can we add to the set of paints, some new paints that do not have a name, but only reference number?

# Back to the paint

Introducing Union types through an example

Type definition	Filtering
type paint =  Blue  Yellow  Red  Number of int	<pre>let is_blue (p:paint):bool =   match p with    Blue → true    Yellow → false    Red → false    Number i → false</pre>

Remark

- Type paint has 3 constant constructors and one non constant constructor.
- Number 14 represents the paint numbered 14 (in an imaginary catalogue)

# Back to the paint

\_

Introducing Union types through an example

Type definition	Filtering
type paint =	let is_blue (p:paint):bool =
Blue	match p with
Yellow	$ $ Blue $\rightarrow$ true
Red	$Yellow \rightarrow false$
(* palette RGB *)	$ \operatorname{Red} \to \operatorname{false}$
RGB of int * int * int	$ $ RGB (r,g,b) $\rightarrow$ r = 0 && g = 0 && b = 255

- Type paint has three constant constructors and one non-constant constructors
- RGB(255,0,0) corresponds to red
- RGB(255,255,0) corresponds to yellow

► ...

#### Union types (aka union type, tagged union, algebraic data types) The general form

#### Syntax of union types:

```
type new_type =
    Identifier_1 of type_1
    Identifier_2 of type_2
    ...
    Identifier_n of type_n
```

Note that:

- ▶ Identifier\_i, *i* ∈ [1, *n*], is an explicit name called a constructor
- the definition "of type\_i" is optional
- type\_i,  $i \in [1, n]$ , can be any (existing) type
- Constructor name must be capitalized

Expression Declaration (of some type t):

```
let expression = Identifier v
```

(if Identifier of tt is a constructor of type t and  ${\tt v}$  is a value of type tt) Remark

Union types are a generalization of enumerated types

### An example: Generalization of int and float

Having two different sets of operations for  ${\tt int}$  and  ${\tt float}$  is sometimes annoying

```
Let's define Numbers = \mathbb{R} \cup \mathbb{N}
```

```
type numbers = INTEGER of int | REAL of float
```

(INTEGER, REAL sont des contructeurs de type)

Let's define additions on two numbers:

```
let add ((nb1,nb2):number*number):number= match (nb1,nb2) with
  |(INTEGER(n1), INTEGER(n2)) \rightarrow INTEGER(n1 + n2)
  |(INTEGER(n), REAL(r)) \rightarrow REAL((float_of_int n) +. r)
  |(REAL(r) , INTEGER(n)) \rightarrow REAL((float_of_int n) +. r)
  |(REAL(r1) , REAL(r2)) \rightarrow REAL(r1 +. r2)
```

Remark Has some advantages and disadvantages

### Another example: Geometry

Type definition	Filtering
<pre>type pt = float * float type figure =     Rectangle of pt * pt     Circle of pt * float     Triangle of pt * pt * pt</pre>	let perimeter (f: figure): float = match f with  Rectangle (p1, 2) $\rightarrow \dots$  Circle (_, r) $\rightarrow \dots$  Triangle (p1, p2, p3) $\rightarrow \dots$

let p1 = 1.0, 2.0 and p2 = 3.9, 2.7 in Rectangle (p1,p2)
let p1 = (1.3, 2.9) in Circle (p1,3.6)

#### Exercise

- ▶ Define the function distance:  $pt \rightarrow pt \rightarrow float$
- The area of any triangle of edges a, b, c is computed using the Héron formula:

$$A = \sqrt{s \cdot (s-a) \cdot (s-b) \cdot (s-c)}$$
 with  $s = \frac{1}{2} \cdot (a+b+c)$ 

Define the function <code>area: figure  $\rightarrow$  float</code>

### Remark: distinguish constructors and unary functions

Constructors and unary functions takes a value of some type and return another value of some other type

A function:

- performs a computation
- cannot be used in pattern matching: the value of all functions is <fun>

A type constructor.

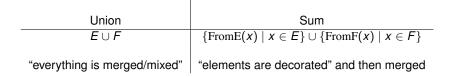

- constructs a value
- can be used in a pattern-matching

DEMO: constructors vs unary functions

### Remark: Difference between union and sum

There is actually a slight difference between union and sum

Consider two sets *E* and *F*:

Second solution is less ambiguous and then preferred by computers

#### Card Game Your choice

1000 bornes

### Playing cards:

#### Images from Wikipedia, Licence CC

# Conclusion

#### Summary:

Richer types:

Туре	Why?
synonym types	informative type names
enumerated types	Finite set of constants
product types	Cartesian product
sum types	Set Union

 Using filtering and pattern matching to define more complex functions (for each of these types)

#### Exercise

Find a (personal) example of objects that can be naturally modelled as a union type. Propose/Invent a function using this type.

# Union types - A review...

#### Example (https://caml.inria.fr/pub/docs/fpcl/fpcl-06.pdf):

A type called identification, values can be:

- either strings (name of an individual),
- or integers (encoding of social security number as a pair of integers)

We need a type containing both int \* int and strings.

id1:identification = Name "Jean"

let id2 = SS (1670728,280305);;

id2:identification = SS (1670728, 280305)

Values id1 and id2 belong to the same type. They may for example be put into lists as in:

[id1;id2];;

▶ -: identification list = [Name "Jean"; SS (1670728, 280305)]
