

## Software security, secure programming (and computer forensics)

### Lecture 4: an overview of Software Security Analysis Techniques

Master M2 on Cybersecurity

Academic Year 2016 - 2017

# Software Security

The ability of a SW to *function correctly* under *malicious attacks*

“function correctly” ?

- ▶ no crash (!), no disclosure/erasure of confidential data
- ▶ no bypass of security policy rules
- ▶ no deviation from intended behavior (arbitrary code execution)

→ what the SW should **not** do ...

“malicious attacks” ?

Well-crafted attack vectors, based on knowledge about:

- ▶ execution platform: libraries, OS/HW protections
- ▶ target software: code, patches
- ▶ up-to-date vulnerabilities and exploit techniques

→ much beyond unexpected input/execution conditions

**secure software  $\neq$  robust/safe/fault-tolerant software**

## Root causes of insecure softwares

“A software flaw that may become a security threat . . .”

≠ kinds of bugs w.r.t security:

- ▶ harmless: only leads to incorrect results or “simple” crash
- ▶ **exploitable**: can lead to unsecure behaviors . . .

### Examples of exploitable vulnerabilities

(combinations of:)

- ▶ invalid memory accesses: buffer overflow, dangling pointers
- ▶ arithmetic overflows
- ▶ race conditions
- ▶ etc.

**Rk:** influence of programming language, compilation tool,  
execution environment (platform, OS, users . . .)

# Vulnerability detection and analysis

## A major security concern . . .

- ▶ 5000 vulns in 2011, 5200 in 2012, 6700 in 2013 ... [Symantec]
- ▶ applications and OS editors, security agencies, defense departments, IT companies, . . .

## . . . and a business !

Some 0-day selling prices [Forbes, 2012]:

Adobe Reader : \$30,000 - Chrome, IE: \$200,000 - ios : \$250,000

## Two distinct problems

1. detection: identify (security related) bugs
2. analysis: evaluate their dangerousness  
Are they exploitable? How difficult is it? Which consequences?

# The current “industrial” practice

## A 2-phase approach

1. (pseudo-random) fuzzing, fuzzing, and fuzzing ...  
↔ to produce a huge number of **program crashes**
2. in-depth *manual* crash analysis  
↔ to identify **exploitable** bugs and obtain PoC exploits (ignoring protections)

## Drawbacks

- ▶ A time consuming activity  
(very small ratio “exploitable flaws/simple bugs” !)  
100,000 open bugs for Linux Ubuntu ; 8000 for Firefox
- ▶ Would require a better **tool assistance** ...  
(e.g., “smart” disassembler, trace analysis, debuggers ?)

**example:** crash of `/bin/make` on Linux ...

# The “academic” research trends

## Re-use and adapt **validation oriented** code analysis techniques

- ▶ static analysis, bounded model-checking
- ▶ test generation:  
symbolic/concolic execution, genetic algos, etc.
- ▶ dynamic (trace based) analysis

## security analysis $\neq$ safety analysis !

- ▶ should be carried on the executable code
- ▶ exploit analysis  $\Rightarrow$  **beyond** source-level semantics  
(understand what can happen **after** an undefined behavior)

Main issue: **scalability** ! ...

DARPA CGC: software security tool competition (1st prize: \$2,000,000)

# Outline

Software Security

**Outline of the next parts of the course**

Disassembling

Oral presentations

## Some security-oriented code analysis techniques

- ▶ **Disassembling**  
from binary code to assembly-level code representation
- ▶ **Fuzzing**  
how to make a program crash ?
- ▶ **Static Analysis**  
analyse an approximation of the code behaviour without executing it
- ▶ **Dynamic Analysis**  
collect (more) useful information at runtime
- ▶ **(Dynamic) Symbolic Execution (DSE)**  
explore a (comprehensive) subset of the execution sequences

And, in addition, an overview of:

- ▶ code (de)-obfuscation techniques
- ▶ code hardening

# Course organization

- ▶ lectures
- ▶ paper exercises
- ▶ **lab sessions** (on tools)  
static analysis, DSE, fuzzing, code instrumentation, ...
- ▶ **oral presentations** (see later)

# Outline

Software Security

```
push    ebp
mov     ebp, esp
movzx   ecx, [ebp+arg_0]
pop     ebp
movzx   dx, cl
lea     eax, [edx+edx]
add     eax, edx
shl     eax, 2
add     eax, edx
shr     eax, 8
sub     cl, al
shr     cl, 1
add     al, cl
shr     al, 5
movzx   eax, al
retn
```

Disassembling !

## Recovering assembly-level code

- ▶ a non trivial task (static disassembling of x86 code **undecidable**)
- ▶ may produce assembly-level IR ( $\neq$  native assembly code)
  - simpler language (a few instruction opcodes), explicit semantics (no side-effects), share analysis back-ends

## Handling assembly-level code

Still a gap between assembly and source-level code ...

- ▶ recovering basic program elements:
  - functions, variables, types, (conditionnal) expressions, ...
- ▶ pervasive address computations (addresses = values)
- ▶ etc.

**Rk:**  $\neq$  between code produced by a compiler and written by hand  
(structural patterns, calling conventions, ...)

## Static Disassembling

Assume “reasonable” (stripped) code only

→ no obfuscation, no packing, no auto-modification, ...

### Enough pitfalls to make it undecidable ...

- ▶ interleavings between code and data segments
- ▶ dynamic jumps (`jmp eax`)
- ▶ variable-length instruction encoding, # addressing modes, ...  
e.g, > 1000 distinct x86 instructions  
1.5 year to fix the semantics of x86 shift instruction at CMU

### Classical static disassembling techniques

- ▶ linear sweep: follows increasing addresses (ex: `objdump`)  
↔ pb with interleaved code/data ?
- ▶ recursive disassembly: control-flow driven (ex: `IDAPRO`)  
↔ pb with dynamic jumps ?
- ▶ hybrid: combines both to better detect errors ...

# Function identification

Retrieve functions boundaries in a stripped binary code ?

Why is it difficult ?

- ▶ not always clean `call/ret` patterns:  
optimizations, multiple entry points, inlining, etc.
- ▶ not always clean code segment layout:  
extra bytes ( $\notin$  any function), non-contiguous functions, etc.

Possible solution ...

- ▶ pattern-matching on (manually generated) binary signatures
  - ▶ simple ones (`push [ebp]`) + proprietary heuristics [IDA, Bap]
  - ▶ standart library function signature database (FLIRT)
- ▶ supervised machine learning classification

→ no “sound and complete” solutions ...

# Variable and type recovery

## 2 main issues

- ▶ retrieve the memory layout (stack frames, heap structure, etc.)
- ▶ infer size and (basic) type of each accessed memory location

## Memory Layout

“addresses” of global/local variables, parameters, allocated chunks

- ▶ static basic access patterns (`epb+offset`) [IDAPro]
- ▶ lightweight static analysis (e.g., intraprocedural data-flow)
- ▶ Value-Set-Analysis (VSA)

## Types

- ▶ dynamic analysis:  
type chunks (library calls) + loop pattern analysis (arrays)
- ▶ static analysis: VSA + Abstract Structure Identification
- ▶ Proof-based decompilation relation inference  
type system + program witness [POPL 2016]

# CFG construction

## Main issue

handling dynamic jumps (e.g., `jmp eax`) due to:

- ▶ `switch` statements (“jump table”)
- ▶ function pointers, trampoline, object-oriented source code, ...

## Some existing solutions

- ▶ heuristic-based approach (“simple” switch statements) [IDA]
- ▶ static analysis: interleaving between VSA and CFG expansion
  - ▶ strided-intervals vs k-sets, refinement-based approach
  - ▶ use of under-approximations ...

**Rk:** may create many program “entry points”  $\Rightarrow$  many CFGs ...

## To continue:

- ▶ Control-Flow Graphs (CFG) and intermediate representation (IR)
  
- ▶ Some basics on x86
  
- ▶ More on disassembling and reverse-engineering
  - ▶ disassembling techniques (and their limitations)
  - ▶ tools
  - ▶ examples

# Outline

Software Security

Outline of the next parts of the course

Disassembling

**Oral presentations**

## Suggested topics (a non limitative list !)

- ▶ Programming languages and/or execution platforms
  - ↔ focus on specific features, explain the strenght/weaknesses, and the associated protections ...
  - ▶ Java / JVM / Android / ...
  - ▶ Rust
  - ▶ JavaScript / PhP / web / ...
- ▶ Protections
  - ▶ Control-Flow Integrity (CFI)
  - ▶ Windows 10 protections
- ▶ Malwares
  - principles, detection and identification techniques
- ▶ Code (de)-obfuscation techniques
- ▶ Vulnerability exploitation techniques
  - Return-Oriented-Programming (ROP), defeating ASLR, etc.
- ▶ Vulnerability on cryptographic functions implementations

# Organisation

One oral presentation per “binôme” (team of 2 students)

## schedule:

- ▶ one 1.30 hour course slot [**before end of november**]  
choose and refine your subject, select resources (docs, tools) on the web  
→ give back 1-2 slides with your subject outline + selected resources
- ▶ one 1.30 hour course slot [**before end of december**]  
discussion about your work
- ▶ 3 hours course dedicated to oral presentations [**before mid-january**]
  - ▶ 15 mn. presentation per binômes (with slides)
  - ▶ **a written report** (3-5 pages)
