Introduction to cryptology

Université Grenoble Alpes – IM²AG

M1 INFO, MOSIG & AM

What are hash functions?

Definition

A(n unkeyed) **hash function** is a mapping $H : \mathcal{M} \rightarrow \mathcal{H}$, with

▶ $\mathcal{M} = \{0, 1\}^{<N}$: the *message space*

▶ $\mathcal{H} = \{0, 1\}^n$ with $N \gg n$: the *digests*

typically $N \geq 2^{64}$

$n \in \{\cancel{128}, \cancel{160}, \cancel{224}, 256, 384, 512\}$

Variants

▶ *extendable-output function* (XOF) $\rightarrow \mathcal{H} = \{0, 1\}^{<n}$

▶ *keyed hash function* $H : \mathcal{K} \times \mathcal{M} \rightarrow \mathcal{H}$

family of hash functions

A hash function is simply a function: when is it *good*?

Usefulness of hash functions

Hash functions are an essential tool underlying most of (modern) cryptography!

- ▶ *Hash-and-sign*
- ▶ Message authentication codes
- ▶ Password hashing (with a grain of salt)
- ▶ Hash-based signatures
- ▶ Commitment
- ▶ Key derivation
- ▶ As one-way functions or *random oracle*
- ▶ ...

RSA signatures, (EC)DSA, ...
HMAC, ... → next lecture!

Efficiency

- ▶ A few dozen cycles per byte
- ▶ Small memory
- ▶ ...

Security of hash functions

Goals

- ▶ We would like $H(x)$ to
 - ▶ uniquely identify x
 - ▶ be much smaller than x
 - ▶ reveal no information on x
- ▶ Impossible: there exist *collisions* $H(x) = H(y)$ while $x \neq y$

Security notions

- ▶ First preimage resistance: given t , *hard* to find m such that $H(m) = t$
- ▶ Second preimage resistance: given m , *hard* to find $m' \neq m$ such that $H(m') = H(m)$
- ▶ Collision resistance: *hard* to find $m \neq m'$ such that $H(m) = H(m')$

Remarks

- ▶ No definition of *hard*
- ▶ Collision resistance $\Rightarrow$ 2nd preimage resistance
- ▶ 2nd preimage is *in some sense* stronger than 1st preimage resistance

H is fixed!

The ideal world: random oracles

Definition

A **random oracle** is a function $H : \mathcal{M} \rightarrow \mathcal{H}$ such that $\forall x \in \mathcal{M}, H(x) \leftarrow \mathcal{H}$

- ▶ As random as possible: each value $H(x)$ is sampled uniformly and independently
- ▶ Used in proof as the *random oracle model* eq. to ideal cipher model
- ▶ Unrealistic but good hash functions are *approximations* whatever this means

Generic attacks

- ▶ 1st preimage: $O(2^n)$ exhaustive search
- ▶ 2nd preimage: $O(2^n)$ *idem*
- ▶ Collision: $O(2^{n/2})$ “birthday attack”

→ A hash function is *good* if the generic attack is (almost) the best one

On the birthday attack

Reminder

- ▶ If $h_1, \dots, h_q \leftarrow \mathcal{H}$, $\Pr[\exists i \neq j, h_i = h_j] \geq \frac{q(q-1)}{4 \cdot 2^n}$ $q \simeq 2^{n/2} \Rightarrow$ collision prob. $\simeq \frac{1}{4}$
- ▶ Sample $\Omega(2^{n/2})$ values x_i : with good probability, $\exists x_i \neq x_j$ s.t. $H(x_i) = H(x_j)$

Space complexity

- ▶ To find a collision, need to store $\Omega(2^{n/2})$ values
- ▶ Floyd's *tortoise and hare* algorithm:
 1. $x_0 \leftarrow \mathcal{M}$
 2. do $(x_i, x_{2i}) \leftarrow (H(x_{i-1}), H(H(x_{i-1})))$ until $x_i = x_{2i}$
 → Only two values to store, same time complexity

Useful collisions

Goal: Find two messages m_0 and m_1 of opposite meanings s.t $H(m_0) = H(m_1)$

- ▶ “I owe 1000€ to Bruno” and “Bruno owes me 1000€”

Method: Produce many variants of m_0 and m_1 until a collision is found

- ▶ “I have a 1000€ debt to Bruno”, “Bruno is 1000€ in debt to me”, ...
- ▶ Variant of birthday bound: find a collision between two lists

Contents

1. Hash functions from compression functions

2. Hash functions from permutations

Compression functions

Definition

A **compression function** is a mapping $f : \{0, 1\}^n \times \{0, 1\}^w \rightarrow \{0, 1\}^n$

- ▶ Family of functions from $\{0, 1\}^n$ to itself
- ▶ Compare to hash functions: fixed-length input
- ▶ Compare to block ciphers: not invertible

Goal

Assuming a *good* f is given, how to construct a *good* hash function?

- ▶ Fixed-size $\rightarrow$ Variable-size
- ▶ Compare to block cipher modes of operation

domain extension

The Merkle-Damgård construction (1989)

- ▶ IV : **fixed initial value** in $\{0, 1\}^n$ part of H 's specification
- ▶ $f : \{0, 1\}^n \times \{0, 1\}^w \rightarrow \{0, 1\}^n$
- ▶ $\text{pad}(m) = m \| 10 \cdots 0 \parallel \langle \text{length of } m \rangle \rightsquigarrow |\text{pad}(m)| = B \times w$
- ▶ $H(m) = f(\cdots f(f(IV, m_1), m_2) \dots, m_B)$

Efficiency

- ▶ B sequential calls to $f \rightarrow \text{OK}$

Merkle-Damgård construction: security

Warm-up: first preimage resistance

If f is 1st preimage resistant, then H is 1st preimage resistant too

Proof by contrapositive.

. Assume that given t , one can compute m s.t. $H(m) = t$

. From m , one can re-compute $H(m)$ and get all the intermediate results h_i .

$\Rightarrow$ Then $t = h_B = f(h_{B-1}, m_B) : (h_{B-1}, m_B)$ is a preimage of t for f .

Merkle-Damgård construction: security

Warm-up: first preimage resistance

If f is 1st preimage resistant, then H is 1st preimage resistant too

Collision resistance

If f is collision resistant, then H is collision resistant too

Proof by contrapositive.

Assume one can compute $m \neq m'$ s.t. $H(m) = H(m')$

$$\begin{aligned} \rightarrow \text{pad}(m) &= m_1 \| \dots \| m_B & \text{pad}(m') &= m'_1 \| \dots \| m'_B \\ &h_1, \dots, h_B & h'_1, \dots, h'_B \end{aligned}$$

$$\text{with } h_B = h'_B = H(m) = H(m')$$

Case 1: $|m| \neq |m'| \leadsto m_B \neq m'_B$, since m_B contains the length of m , and the same for m'
 $\rightarrow f(h_{B-1}, m_B) = f(h'_{B-1}, m'_B)$ is a collision for f

Case 2: $|m| = |m'|$. Take b maximal s.t. $(h_{b-1}, m_b) \neq (h'_{b-1}, m'_b)$
 $\rightarrow f(h_{b-1}, m_b) = h_b = h'_b = f(h'_{b-1}, m'_b)$ is a collision for f .

Case 1:

Case 2:

Merkle-Damgård construction: 2nd preimage vulnerability

Idea of an attack by Kelsey & Schneier (2005)

Goal: Given m , find $m' \neq m$ s.t. $H(m') = H(m)$

► Find m_0 such that $f(h_0, m_0) = h_i$ for any h_i $\simeq 2^w/B$

Merkle-Damgård construction: 2nd preimage vulnerability

Idea of an attack by Kelsey & Schneier (2005)

Goal: Given m , find $m' \neq m$ s.t. $H(m') = H(m)$

- Find m_0 such that $f(h_0, m_0) = h_i$ for any h_i $\simeq 2^w/B$
 - $m_0 || m_{i+1} || \dots || m_B$ almost works but m_B contains the wrong length

Merkle-Damgård construction: 2nd preimage vulnerability

Idea of an attack by Kelsey & Schneier (2005)

Goal: Given m , find $m' \neq m$ s.t. $H(m') = H(m)$

- ▶ Find m_0 such that $f(h_0, m_0) = h_i$ for any h_i $\simeq 2^w/B$
 - ▶ $m_0 \| m_{i+1} \| \dots \| m_B$ almost works but m_B contains the wrong length
- ▶ Works if we can find a family of m_0 's of variable lengths
 - ▶ from fixed points $h_f = f(h_f, m_f)$ $\simeq 2^{n/2}$ (in some cases)
 - ▶ from multicollisions: $m^1, \dots, m^{2^t}$ s.t. $f(h_0, m^1) = \dots = f(h_0, m^{2^t})$ $\simeq t \cdot 2^{n/2}$

$\Rightarrow$ 2nd preimage in $\simeq 2^w/B + (t \times) 2^{n/2}$ instead of $O(2^n)$

Merkle-Damgård construction: security summary

How vulnerable for 2nd preimage?

- ▶ Kelsey-Schneier attack requires to find collisions in f
- ▶ Actually: a 2nd preimage *is* a collision!
 - ▶ Reduction to collision resistance of $H \rightarrow$ collision resistance of f
 - ▶ *birthday security* $\simeq 2^{n/2}$

Patch: Chod-MD / Wide-pipe MD (2005)

- ▶ Use $f : \{0, 1\}^n \times \{0, 1\}^w \rightarrow \{0, 1\}^{n+k}$
- ▶ Only keep the first n bits of $f(h_{i-1}, m_i)$ as input to next f
- ▶ Very strong provable guarantees

Summary

- ▶ Same collision resistance for H as for f
- ▶ Same 1st preimage resistance for H as for f
- ▶ 2nd preimage resistance of H related to collision resistance of f

How to design compression functions?

Davies-Meyer construction

$$f(h_{i-1}, m_i) = E(m_i, h_{i-1}) \oplus h_{i-1}$$

Matyas-Meyer-Oseas construction

$$f(h_{i-1}, m_i) = E(h_{i-1}, m_i) \oplus m_i$$

Security

- ▶ Systematic analysis of possible constructions (“PGV constructions”)
- ▶ Rigorous proofs in the **ideal cipher model**
 - ▶ Not sufficient since actual block ciphers are not ideal!
 - ▶ Example: XBOX used a Davies-Meyer based construction with non-ideal cipher

Final words on Merkle-Damgård construction

- ▶ Many examples: MD4, MD5, SHA-0, SHA-1, SHA-2, ...
- ▶ MD5 failure:
 - ▶ 1992: Designed by Rivest
 - ▶ 1993: Collision attack on the compression function
 - ▶ 2005: Collision attack on the hash function
 - ▶ 2007-9: Practical useful collisions

Used up to 2008 (at least), while alternatives were available since (at least) 1996!

- ▶ Another bad example: Git chose SHA-1 in 2005 while weaknesses were known

Lessons

- ▶ Care about attacks! Even *theoretical*!
- ▶ Most (every?) weaknesses can evolve to damaging attacks

Don't design your own crypto!

Contents

1. Hash functions from compression functions

2. Hash functions from permutations

Hash function from a permutation

Definition

A permutation of $\{0, 1\}^n$ is an one-to-one correspondence $P : \{0, 1\}^n \rightarrow \{0, 1\}^n$

- ▶ No key – no security notion such as PRP
- ▶ Ex.: for any block cipher, $E(0, \cdot)$ is a permutation
- ▶ Possible view: block cipher where key and plaintext are given together
- ▶ A permutation is invertible, but its inverse is often non necessary

Construction of a hash function

- ▶ *Sponge* construction : permutation $\rightarrow$ hash function
- ▶ Same general idea (but completely different construction) than Merkle-Damgård

The sponge construction

1. $m_1 \parallel \dots \parallel m_t \leftarrow \text{pad}(m) = m \parallel 10 \dots 0$

$|\text{pad}(m)| = t \cdot r$

2. $y_0 \leftarrow 0^n$

3. for $i = 1$ to t : $y_i \leftarrow P(y_{i-1} \oplus (m_i \parallel 0^c))$

absorbing phase

4. $z_1 \leftarrow y_t$

5. for $i = 2$ to λ : $z_i \leftarrow P(z_{i-1}); h_i \leftarrow \text{first } v \text{ bits of } z_i$

squeezing phase

6. return $H(m) = h_1 \parallel h_2 \parallel \dots \parallel h_\lambda$

Sponge features

Sponge are convenient!

- ▶ If P is a random permutation, H is indifferentiable from a RO
- ▶ Flexible:
 - ▶ For a fixed permutation size, values of r , v and $\lambda \rightarrow$ speed/security trade-off
 - ▶ Natively a XOF (variable λ)
- ▶ Simplicity: easier to design a (good) permutation

SHA-3 – Keccak

- ▶ Hash function using the sponge construction, from a permutation of $\{0, 1\}^{1600}$
- ▶ Standardized by NIST, after an academic competition (2008-2012)
- ▶ Best current choice for a hash function
- ▶ Four main variants: SHA3-224, SHA3-256, SHA3-384 and SHA3-512

If you need a hash function, use SHA-3!

Sponge security proof sketch

Theorem

If P is a uniform random permutation and $\lambda = 1$, an adversary making q queries to $P^\pm$ has probability $\leq \frac{q^2}{2^v} + \frac{q^2}{2^c}$ to produce a collision.

Admitted claim. If $\mathcal{A}$ produces a collision, at least one of the following events occurs:

- E_1 The adv. makes a query to $P^\pm$ whose result ends with 0^c
- E_2 The adv. makes 2 queries to P whose results agree on their first v bits
- E_3 The adv. makes 2 queries to $P^\pm$ whose results agree on their last c bits

Proof of the theorem. $\Pr[\mathcal{A} \text{ produces a coll.}] \leq \Pr[E_1 \vee E_2 \vee E_3] \leq \Pr[E_1] + \Pr[E_2] + \Pr[E_3]$

$$- \Pr[E_1] \leq \frac{q}{2^c}$$

$$- \Pr[E_2] \leq \sum_{i < j} \Pr[i^{\text{th}} \text{ and } j^{\text{th}} \text{ queries agree on their first } v \text{ bits}] \leq \binom{q}{2} \frac{2^{n-v}-1}{2^n-1} \leq \frac{q(q-1)}{2^v}$$

$$- \Pr[E_3] \leq \frac{q(q-1)}{2^c}$$

Conclusion

Two main families

- ▶ Merkle-Damgård construction from a compression function
- ▶ Sponge construction from a random permutation
- ▶ Many broken constructions, few good ones...

... therefore:

Don't design crypto yourself!

- ▶ No generic way to build a hash function
- ▶ Every small detail counts!

Use SHA-3 (or maybe SHA-2)

- ▶ Don't use MD5!
- ▶ Don't use SHA-1!
