Adaptive redundant residue system for cloud computing: a processor-oblivious and fault-oblivious technology

> Jean-Louis ROCH INRIA **MOAIS** team, LIG lab. Grenoble Université, France

Joint work with C. Pernet [1], T. Roche [1, 4], S. Varrette [3, 2], S. Jafar [2], A. Krings [2], B. Cunche [4], M. Khonji[1], T. Stalinski[1]

Computer Science Dept, University of Western Ontario Monday January 24, 2011

Plan

Introduction

High performance computing and cloud

Related works on trusting the clouds Cloud computing and performance ABFT

Redundant residue codes

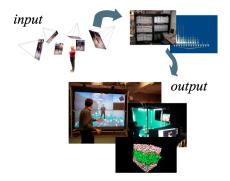

Homomorphic residue system Over Z: Mandelbaum algorithm Over K[X]: Reed Solomon point of view Generalization

Adaptive approach

First approach and the gap Experiments Early termination

Context: High Performance Interactive Computation

INRIA - LIG Moais team

- Performance: multi-criteria trade-off

 — computation latency and computation bandwidth
- Application domains: interactive simulations (latency), computer algebra (bandwidth), ...

HPC platforms

From low computation latency to high computation bandwidth

- Parallel chips & multi/many-core architectures: multicore cpu, GP-GPU, FPGA, MPSoCs
- Servers: Multi-processor with "sharedi" memory (CPUs + GPUs+...)
- Clusters: 72% of top 500 machines, Heterogeneous (CPUs + GPUs + ...)
 E.g. Tianhe-1A, ranked 1 in TOP500 nov 2010: 4.7 PFlops

Global computing platforms: grids, P2P, clouds
 E.g. BOINC : in April 2010= 5.1 PFlops

Cloud / Global computing platforms

Applications

Data sharing (1980's), Data storage, Computation (1990's)

"Unbound" computation bandwidth

Volunteer Computing: steal idle cycles through the Internet

- Folding@Home 5 PFLOPS, as of March 17, 2009
- MilkyWay@Home 1.6 PFLOPS, as of April 2010 Thanks to GPUs !

Grid or cloud ?

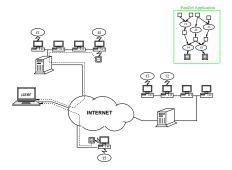

Beyond computation bandwidth, two important criteria:

- granularity: how small is the smallest bit of computational resource that you can buy;
- speed of scaling: how long it takes to increase the size of available resources.

Global computing architecture and trust

Open platforms are subject to attacks:

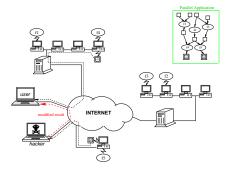

- machine badly configured, over clocking,
- malicious programs,
- client patched and redistributed: possibly large scale

Global computing architecture and trust

Open platforms are subject to attacks:

- machine badly configured, over clocking,
- malicious programs,
- client patched and redistributed: possibly large scale

Global computing platforms: drawbacks

Peers volatility

Peers can join/leave at any time.

Faults, crashes

As the number of nodes increases, the number of faults, process crashes increases as well.

Trust in Peers

Malicious Peers (intentionally or infected by malwares).

- Random Crashes
- Random Forgeries
- Byzantine behaviour (e.g., Peers collusion)

Related work: trusting the Cloud

Volatility

Replication, (partial) Re-execution, Checkpoint/restart

Trust

- Challenges / blacklisting [Sramenta&ak 01]
- Replication of tasks:
 - BOINC: credit evaluation
 - Byzantine agreement: n processes for n/3 faulty (one-third faulty replicas [Lamport82s])
- Check / Verification using postconditions (on the output) [Blum97]

Related work: trusting the Cloud

Volatility

Replication, (partial) Re-execution, Checkpoint/restart

Trust

- Challenges / blacklisting [Sramenta&ak 01]
 ⇒expensive
- Replication of tasks:
 - BOINC: credit evaluation
 Attacks can be adjusted
 - Byzantine agreement: n processes for n/3 faulty (one-third faulty replicas [Lamport82s])
 ⇒often expensive
- Check / Verification using postconditions (on the output) [Blum97]
 - \Rightarrow not always possible

Related work: trusting the Cloud

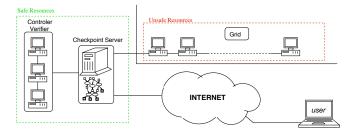

- Without trust assumptions, basic properties (eg integrity, atomicity, weak consistency, ...) cannot be guaranteed
- But, by maintaining a small amount of trusted memory and trusted computation units, well-known cryptographic methods reduce the need for trust in the storage [Cachin&al. ACM SIGACT 2009]
 - integrity by storing small hash (hash tree for huge data)
 - authentication of data
 - proofs of retrievability (POR) and of data possession (PDP)

(日) (日) (日) (日) (日) (日) (日)

Considered cloud computing platform

- \implies Two disjoint set of resources:
 - ► U: The cloud, unreliable
 - R: Resources blindly trusted by the user (reliable), but with limited computation bandwidth

interconnected through a stable memory

Plan

Introduction

High performance computing and cloud

Related works on trusting the clouds Cloud computing and performance ABFT

Redundant residue codes

Homomorphic residue system Over Z: Mandelbaum algorithm Over K[X]: Reed Solomon point of view Generalization

Adaptive approach

First approach and the gap Experiments Early termination

How to take benefit of the Cloud for HPiC?

Performance and correction

▶ Performance: massive parallelism (*work* ≫ *depth*) → workstealing, adaptive scheduling [Leiserson&al. 2007]

(日) (日) (日) (日) (日) (日) (日)

- ► Correction of the results: proof → verifications on *R* (e.g. randomized checking)
- ► Fault tolerance: to support resilience and/or errors → ABFT: Algorithm Based Fault Tolerance

Execution time model on the cloud

Resource type	average computation bandwidth per proc	Total computation bandwidth	Usage
Cloud U	Πυ	Π_U^{tot}	computation
Client R	Π _R	Π_{R}^{tot}	certification

bandwidth: number of unit operations per second

Bound on the time required for computation+certification

Based on work-stealing, with high probability [Bender-Rabin02] :

Execution time
$$\leq \frac{W_c}{\Pi_U^{tot}} + \mathcal{O}\left(\frac{D_c}{\Pi_U}\right) + \frac{W_r}{\Pi_R^{tot}} + \mathcal{O}\left(\frac{D_r}{\Pi_R}\right).$$

Notations and target context:

- W_c (resp. D_c) = total work (resp. depth) executed on the cloud U;
- W_r (resp. D_r) = total work (resp. depth) executed on the client *R*;
- ► Target context: $W_c = O(W_1^{1+\epsilon})$; $D_c \ll W_c$; $W_r, D_r \ll D_c$.
- ► Correction: may be computed either on *R*, or on *U*, or on both.

Example: Matrix-vector product

Idea: incorporate redundancy in the algorithm [Huang&Abraham 98] [Saha 2006] [Dongarra & al. 2006] ⇒use properties specific to the problem

◆□▶ ◆□▶ ▲□▶ ▲□▶ ▲□ ◆ ○○

Example: Matrix-vector product

- pre-compute the product $B = A \times \begin{bmatrix} I & R \end{bmatrix}$
- compute x = uB in parallel
- decode/correct x

Summary

Typical considered global computation

 Interactive computation between R (reliable) and the cloud U (unreliable);

- On U: Computations loosely coupled and fault tolerant
- On R: submission of the computation correction (if not too much errors) verification (if not too much errors)
- \hookrightarrow homorphic residue system

Plan

High performance computing and cloud

Related works on trusting the clouds Cloud computing and performance ABFT

Redundant residue codes

Homomorphic residue system Over Z: Mandelbaum algorithm Over K[X]: Reed Solomon point of view Generalization

Adaptive approach

First approach and the gap Experiments Early termination

Homomorphic residue system

- One-to-one mapping Φ from E to E₁ × ... × E_n that preserves the algebraic structure
- $\Phi: x \mapsto x_1, \dots, x_n$: projection $\Phi^{-1}(x_1, \dots, x_n)$: lifting
- ► \hookrightarrow For a fixed computation *P* (straight-line program): For input *x*: $\Phi(P_x) = \Phi(P)_{x_1}, \dots, \Phi(P)_{x_n}$.
- Classical examples: residue number/polynomial systems:
 - ▶ Polynomials: Φ(Q) = (Q(a₁),..., Q_{(a_n)) [evaluation/interpolation]}
 - Integers: Φ(x) = (x mod a₁,...,x mod a_n) a₁,..., a_n: residue number system (relatively prime)

Integers: Chinese remainder algorithm

$$\mathbb{Z}/(n_1 \dots n_k)\mathbb{Z} \equiv \mathbb{Z}/n_1\mathbb{Z} \times \dots \times \mathbb{Z}/n_k\mathbb{Z}$$

Computation of y = f(x) over \mathbb{Z}

beginCompute a bound β on max(|f|);Pick $n_1, \ldots n_k$, pairwise prime, s.t. $n_1 \ldots n_k > \beta$;for $i = 1 \ldots k$ do $\carcel{eq:compute}{l}$ Compute $y_i = f(x \mod n_i) \mod n_i$ Compute $y = CRT(y_1, \ldots, y_k)$ end

$$CRT: \mathbb{Z}/n_1\mathbb{Z} \times \cdots \times \mathbb{Z}/n_k\mathbb{Z} \to \mathbb{Z}/(n_1 \dots n_k)\mathbb{Z}$$
$$(x_1, \dots, x_k) \mapsto \sum_{i=1}^k x_i \Pi_i Y_i \mod \Pi$$
where
$$\begin{cases} \Pi = \prod_{i=1}^k n_i \\ \Pi_i = \Pi/n_i \\ Y_i = \Pi_i^{-1} \mod n_i \end{cases}$$

Integers: Chinese remainder algorithm

$$\mathbb{Z}/(n_1 \dots n_k)\mathbb{Z} \equiv \mathbb{Z}/n_1\mathbb{Z} \times \dots \times \mathbb{Z}/n_k\mathbb{Z}$$

Computation of y = f(x) over \mathbb{Z}

begin

Compute a bound β on max(|f|); Pick $n_1, \ldots n_k$, pairwise prime, s.t. $n_1 \ldots n_k > \beta$; for $i = 1 \ldots k$ do Compute $y_i = f(x \mod n_i) \mod n_i$; /* Evaluation */ Compute $y = CRT(y_1, \ldots, y_k)$; /* Interpolation */ end

$$CRT: \mathbb{Z}/n_1\mathbb{Z} \times \cdots \times \mathbb{Z}/n_k\mathbb{Z} \to \mathbb{Z}/(n_1 \dots n_k)\mathbb{Z}$$
$$(x_1, \dots, x_k) \mapsto \sum_{i=1}^k x_i \Pi_i Y_i \mod \Pi$$
where
$$\begin{cases} \Pi = \prod_{i=1}^k n_i \\ \Pi_i = \Pi/n_i \\ Y_i = \Pi_i^{-1} \mod n_i \end{cases}$$

 \Rightarrow deterministic algorithm

Early termination

Classic Chinese remaindering

- bound β on the result
- Choice of the n_i : such that $n_1 \dots n_k > \beta$

⇒deterministic algorithm

Early termination

- For each new modulo n_i:
 - reconstruct $y_i = f(x) \mod n_1 \times \cdots \times n_i$
 - If $y_i = y_{i-1} \Rightarrow$ terminated

 \Rightarrow if n_i chosen at random: randomized algorithm (Monte Carlo)

Early termination

Classic Chinese remaindering

- bound β on the result
- Choice of the n_i : such that $n_1 \dots n_k > \beta$

⇒deterministic algorithm

Early termination

- For each new modulo n_i:
 - reconstruct $y_i = f(x) \mod n_1 \times \cdots \times n_i$
 - If $y_i = y_{i-1} \Rightarrow$ terminated

 \Rightarrow if n_i chosen at random: randomized algorithm (Monte Carlo)

Advantage:

- Adaptive number of moduli depending on the output value
- Interesting when
 - pessimistic bound: sparse/structured matrices, ...
 - no bound available

Redundant residues codes

Principle:

- Chinese remaindering based parallelization
- Byzantines faults affecting some modular computations

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● のへで

Mandelbaum algorithm over \mathbb{Z}

Definition

$$(n,k)\text{-code: } C = \begin{cases} (x_1,\ldots,x_n) \in \mathbb{Z}_{p_1} \times \cdots \times \mathbb{Z}_{p_n} \text{ s.t. } \exists !x, \begin{cases} x < p_1 \ldots p_k \\ x_i = x \mod p_i \forall i \end{cases} \end{cases}$$

Property

$X \in C$ iff $X < \prod_k$.

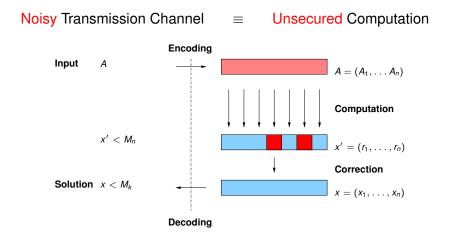

Redundancy : r = n - k

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● のへで

Transmission Channel \equiv Computation

Noisy Transmission Channel = Unsecured Computation

◆□▶ ◆□▶ ◆ □▶ ◆ □▶ ○ □ ○ のへぐ

Properties of the code

Error model:

- Error: E = X' X
- ▶ Error support: $I = \{i \in 1 ... n, E \neq 0 \mod p_i\}$

◆□▶ ◆□▶ ▲□▶ ▲□▶ ▲□ ◆ ○ ◆ ○ ◆

• Impact of the error: $\Pi_F = \prod_{i \in I} p_i$

Properties of the code

Error model:

- ► Error: *E* = X' − X
- Firror support: $I = \{i \in 1 \dots n, E \neq 0 \mod p_i\}$
- Impact of the error: $\Pi_F = \prod_{i \in I} p_i$

Detects up to *r* errors:

```
If X' = X + E with X \in C, \#I \leq r,
```

 $X' > \prod_k$.

◆□▶ ◆□▶ ▲□▶ ▲□▶ ▲□ ◆ ○○

- Redundancy r = n k, distance: r + 1
- ► ⇒can correct up to $\lfloor \frac{r}{2} \rfloor$ errors in theory
- More complicated in practice...

Correction

 $\blacktriangleright \forall i \notin I : E \mod p_i = 0$

• *E* is a multiple of Π_V : $E = Z \Pi_V = Z \prod_{i \notin I}$

•
$$gcd(E,\Pi) = \Pi_V$$

Mandelbaum 78: rational reconstruction

$$X = X' - E = X' - Z\Pi_{v}$$
$$\frac{X}{\Pi} = \frac{X'}{\Pi} - \frac{Z}{\Pi_{F}}$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● のへで

$$\Rightarrow |\frac{X'}{\Pi} - \frac{Z}{\Pi_F}| \le \frac{1}{2\Pi_F^2}$$

$$\Rightarrow \frac{Z}{\Pi_F} = \frac{E}{\Pi} \text{ is a convergent of } \frac{X'}{\Pi}$$

$$\Rightarrow \text{rational reconstruction of } X' \mod \Gamma$$

Correction capacity

Mandelbaum 78:

- 1 symbol = 1 residue
- ▶ Polynomial algorithm if $e \le (n-k) \frac{\log p_{\min} \log 2}{\log p_{\max} + \log p_{\min}}$
- worst case: exponential (random perturbation)

Goldreich Ron Sudan 99 weighted residues ⇒equivalent Guruswami Sahai Sudan 00 invariably polynomial time

Correction capacity

Mandelbaum 78:

- 1 symbol = 1 residue
- ▶ Polynomial algorithm if $e \le (n-k) \frac{\log p_{\min} \log 2}{\log p_{\max} + \log p_{\min}}$
- worst case: exponential (random perturbation)

Goldreich Ron Sudan 99 weighted residues ⇒equivalent Guruswami Sahai Sudan 00 invariably polynomial time

Interpretation:

- Errors have variable weights depending on their **impact** $\Pi_F = \prod_{i \in I} p_i$
- Example: $X = 20, p_1 = 2, p_2 = 3, p_3 = 101$
 - 1 error on X mod 2, or X mod 3, can be corrected
 - but not on X mod 101

(n,k) amplitude code $C = \{x \in \mathcal{A} : \nu(x) < \kappa\},\ n = \log_2 \Pi, k = \log_2 \kappa.$

Property (Quasi MDS)

d > n - k in general, and $d \ge n - k + 1$ over K[X].

⇒correction rate = maximal amplitude of an error that can be corrected

Advantages

- Generalization over any Euclidean ring
- Natural representation of the amount of information

▲□▶▲□▶▲□▶▲□▶ □ のQ@

- No need to sort moduli
- Finer correction capacities

Advantages

- Generalization over any Euclidean ring
- Natural representation of the amount of information
- No need to sort moduli
- Finer correction capacities
- Adaptive decoding: taking advantage of all the available redundancy
- Early termination: with no a priori knowledge of a bound on the result

Interpretation of Mandelbaum's algorithm

Remark

Rational reconstruction \Rightarrow Partial Extended Euclidean Algorithm

Property

The Extended Euclidean Algorithm, applied to (E, Π) and to $(X' = X + E, \Pi)$, performs the same first iterations until $r_i < \Pi_V$.

$$u_{i-1}E + v_{i-1}\Pi = \Pi_{v} | u_{i-1}X' + v_{i-1}\Pi = r_{i-1}$$
$$u_{i}E + v_{i}\Pi = 0 | u_{i}X' + v_{i}\Pi = r_{i}$$
$$\Rightarrow u_{i}X = r_{i}$$

Amplitude decoding, with static correction capacity

Amplitude based decoder over R

Data: Π, X' **Data**: $\tau \in \mathbb{R}_+ \mid \tau < \frac{\nu(\Pi)}{2}$: bound on the maximal error amplitude **Result**: $X \in R$: corrected message s.t. $\nu(X)4\tau^2 \leq \nu(\Pi)$ begin $\alpha_0 = 1, \beta_0 = 0, r_0 = \Pi;$ $\alpha_1 = 0, \beta_1 = 1, r_1 = X'$ i = 1: while $(\nu(r_i) > \nu(\Pi)/2\tau)$ do Let $r_{i-1} = q_i r_i + r_{i+1}$ be the Euclidean division of r_{i-1} by r_i ; $\alpha_{i+1} = \alpha_{i-1} - \mathbf{q}_i \alpha_i;$ $\beta_{i+1} = \beta_{i-1} - q_i \beta_i;$ i = i + 1: return $X = -\frac{r_i}{\beta_i}$ end

reaches the quasi-maximal correction capacity

◆□▶ ◆□▶ ▲□▶ ▲□▶ ▲□ ◆ ○ ◆ ○ ◆

Amplitude decoding, with static correction capacity

Amplitude based decoder over R

Data: Π, X' **Data**: $\tau \in \mathbb{R}_+ \mid \tau < \frac{\nu(\Pi)}{2}$: bound on the maximal error amplitude **Result**: $X \in R$: corrected message s.t. $\nu(X)4\tau^2 \leq \nu(\Pi)$ begin $\alpha_0 = 1, \beta_0 = 0, r_0 = \Pi;$ $\alpha_1 = 0, \beta_1 = 1, r_1 = X'$ i = 1: while $(\nu(r_i) > \nu(\Pi)/2\tau)$ do Let $r_{i-1} = q_i r_i + r_{i+1}$ be the Euclidean division of r_{i-1} by r_i ; $\alpha_{i+1} = \alpha_{i-1} - \mathbf{q}_i \alpha_i;$ $\beta_{i+1} = \beta_{i-1} - q_i \beta_i;$ i = i + 1;return $X = -\frac{r_i}{\beta_i}$ end

- reaches the quasi-maximal correction capacity
- requires a *a priori* knowledge of τ

⇒How to make the correction capacity adaptive?

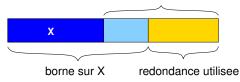

Adaptive approach

Multiple goals:

- With a fixed n, the correction capacity depends on a bound on X
 - ⇒pessimistic estimate
 - ⇒how to take advantage of all the available redundancy?

redondance effective utilisable

▲□▶▲□▶▲□▶▲□▶ □ のQ@

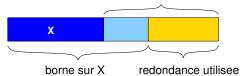

Adaptive approach

Multiple goals:

- With a fixed n, the correction capacity depends on a bound on X
 - ⇒pessimistic estimate
 - ⇒how to take advantage of all the available redundancy?

Allow early termination: variable n and unknown bound

Redundant residue codes

Homomorphic residue system Over Z: Mandelbaum algorithm Over K[X]: Reed Solomon point of view Generalization

Adaptive approach

First approach and the gap Experiments Early termination

A first adaptive approach

Termination criterion in the Extended Euclidean alg.:

•
$$\alpha_{i+1}\Pi - \beta_{i+1}E = 0$$

 $\Rightarrow E = \alpha_{i+1}\Pi/\beta_{i+1}$
 \Rightarrow test if β_j divides Π

- check if X satisfies: $\nu(X) \leq \frac{\nu(\Pi)}{4\nu(\beta_i)^2}$
- But several candidates are possible
 discrimination by a post-condition on the result

Conclusion

Residue systems : "technology" suited to cloud computing: parallelism, fault-tolerant, verification

New metric for redundant residue codes:

- Unification with finer bounds on the correction capacities
- Enables adaptive decoding

Adaptative decoding and early termination

- Gap method: limited overhead, better performances
- Framework for interactive computing with a cloud

Perspective

- ABFT in exact linear algebra, determinant [LinBox]
- ABFT with (exact) floating point arithmetic
- Theoretical efficiency of the gap method,
- Generalization to adaptive list decoding [Sudan, Guruswami]
